AAZ65654 to AAZ69578 represent human biallelic markers, from the present invention, which contain a polymorphic base at position 24 of their nucleotide sequences. AAZ69579 to AAZ77440 represent amplification of primers for the biallelic markers. The biallelic markers of the invention have a variety of uses: they can be used for high density mapping of the human genome, and in complex association studies and haplotyping studies which are useful in determining the genetic basis for disease states. Compositions and methods of the invention can also be useful for the identification of the targets for the development of pharmaceutical agents and diagnostic methods, as well as the characterisation of the defence in the characterisation of the pharmaceutical agents acting on a disease as well as other treatment. The The SEQ ID NOS 2852, 2913, 2974, 3035, 3096, 3157, 3227, 3297 and the passon invention a sequence in the Sequence Listing from the present in the Sequence Listing from the constant in the sequence Listing from the sequence in the sequence Listing from the sequence in the sequence Listing from the constant in the sequence Listing from the sequence in the seq
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Novel biallelic markers used to construct a high density disequilibrium
                                                                                                                           Human biallelic marker upstream amplification primer SEQ ID NO:7262.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            The invention relates to a mammalian K+ channel protein with two pore domains, called TREX2 (TWIK-Related K+ Channel). The protein produces currents whose current-voltage relationship is slightly inwardly rectifying in high symmetrical K+ conditions. TREK2 is a member of the fatty acid-activated and mechanosensitive K+ channel family. TREK-2 gene footsed on chromosome 1431 is abundantly expressed in Kidney, pencreas and moderately in testis, brain, colon and small intestine. The mammalian K+ channel protein is useful in methods for screening various compounds. In particular, the protein is useful in methods for identifying biologically active compounds with anaesthetic properties. The present sequence is reverse transcription (RT) PCR primer used for analysing human TREK-2 gene exon-intron-exon DNA sequence used in the invention
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                New mammalian K+ channel protein with two pore domains, for screening various compounds, particularly for identifying biologically active compounds with anesthetic properties.

                                                                                                                                                                                                                                                                                ô
                                                                                                                                                                                                                The invention relates to Cryptosporidium parvum S60 potential vaccine antigen and its corresponding DNA molecule. S60 antigens are used in vaccine preparations for immunising animals. preferably human, against Cryptosporidium. The S60 protein is processed into two glycoproteins S15 and S45. This S45 and S15 glycoproteins behave as a single membrane glycoprotein S60. S60 vaccine antigen is used for treating intestinal infections such as diarrhoea in immunosuppressed patients e.g., AIDS forguized Immuno Befliciancy Syndrome), cancer patients and recipients of sequencing Cryptosporidium parvum S60 gene
                                                                                                                                                             nucleic acids encoding antigenic polypeptides of Cryptosporidium in antigenic preparations for immunizing animals against

The cell is then lysed by chemical, enzymatic or physical agents and solubilised by exposing it to a denaturing agent, a reducing agent and a cysteine blocking agent, and is refolded into a bhologically active form by reducing agent, concentrations of denaturing and reducing agents. The protein may be to the growth hormone supergene family or may be an anti-angiogenesis to the growth hormone supergene family or may be an anti-angiogenesis factor. The method is useful for preparing a refolded, soluble form of an insoluble or aggregated protein. The proteins of the invention can act as delivery vehicles for enhancement of the circulatory half-life of the
                                                                                                                                                                                                                                                                                              The present sequence is a primer used in a method for monitoring antihepatitis B virus (HBV) drug resistance in a patient by genetic detection of any one of mutations L528M, M552V/I and/or V/L/M555I in HBV DNA polymerase in a biological sample from the patient. The method is useful in the field of genetic detection of anti-HBV drug resistance during HBV therapy. The method is rapid, reliable and precise
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Making and refolding insoluble or aggregated proteins having free cysteine by exposing host cell expressing protein to cysteine blocking agent, and exposing to cysteine reactive group to increase their effectiveness.
                                                                 Monitoring anti-HBV drug resistance by genetic detection of mutations DNA polymerase of HBV in patient's sample, involves hybridizing the polymucleic acids of the sample with a probe and detecting the hybrid.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 88;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               .;

Primer #2 (5'-3618-3639-3', see AAQ32872) was used with minus strand apprimer # (3'-420-4241-5', see AAQ32874) to amplify son 4 of the human apolipoprotein E gene. The epsilon 7 mismatch mutation occurs in this region, at position 4141 and 4144. A set of four oligonucleotide probes was prepared to distinguish the wild type from the mutant base at the mismatch position for both the plus and the minus strands. The probe set AAQ32881-2 and AAQ32889-90 hybridises to nucleotides 4136-4149 of ApoE
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            anchored polymerase chain reaction; APCR; apoE; mismatch; epsilon 2; epsilon 4; epsilon 5; epsilon 7; ss.

therapeutics that are attached or for directing delivery of a specific target within the body. Sequences ABK16774-ABK16852 represent PCR primers used in synthesis of the proteins
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       This probe is used to screen a human liver cDNA library for the presence of a clone (pFRTXI) conteg. the codding information for human factor IX. The recombinant DNA clone is useful for detect- ing mutations or other genetic deficiencies concerned with factor IX. It can also be used to diagnose blood clotting deficiencies e.g. haemophilia B. The use of recombinant DNA methods results in the large scale expression of hFIX polypeptides. See also AAQ10577 and AAQ10579

                                                                                                                                                                                                                                                                                                                                                                        ö
                                                                                                                                                             Primer #2 (5'-3618-3639-3', see AAQ32872) was used with minus strand primer #4 (3'-4220-4241-5', see AAQ32874) to amplify exon 4 of the human apolipoprotein E gene. The epsilon 7 mismatch mutation occurs in this region, at position 4141 and 4144. A set of four oligonucleotide probes was prepared to distinguish the wild-type from the mutant base at the mismatch position for both the plus and the minus strands. The probe set AAQ32881-2 and AAQ32889-90 hybridises to nucleotides 4136-4149 of ApoE
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The sequence is that of a polynucleotide probe which may be used in the detection of new hypervariable regions (HVR) in a DNA sequence. HVR represent a fingerprint useful in e.g. forensic science, paternity testing, animal breeding, etc. The probe may be used as part of a method for the efficient detection in humans or other animals, without the use of mini-satellites or primary enrichment. This sequence represents a probe for a wild type HIV reverse
transcriptase (RT) gene fragment. This sequence can be used in the method
cof the invention for determining the susceptibility to antiviral drugs of
viruses which contain RT genes and are present in a biological sample. It
comprises: (1) releasing, isolating or concentrating the polymucleic
acids present in a sample; (2) amplifying the relevant part of the RT
genes present with at least one sultable primer pair; (3) hybridising the
CC genes present with at least one sultable primer pair; (3) hybridising the
CC gapable of simultaneously hybridising to their respective target regions
CC dapable of simultaneously hybridising to their respective target regions
CC dapable of simultaneously hybridising of the irrespective target regions
CC chomologous targets, or with the probes hybridising specifically with a
CC sequence complementary to any of the target sequence at
CC hybrids formed in steep (3); and (4) inferring the nucleotide sequence at
CC the codons of interest (codons 38-44, 47-53, 65-72, 73-77, 148-154, 180-
CC interest and/or antiviral drug resistance spectrum, and possible the type
CC of viral isolates involved from the differential hybridisation signals
CC obtained in step (4). The method is specifically used to detect antiviral
CC drug resistant strains of viruses containing RT genes, especially HIV
C retroviruses and Hepadnaviridae. The method can also be used for

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         This sequence represents a probe for a wild type HIV reverse transcriptase (RT) gene fragment. This sequence can be used in the method transcriptase (RT) gene fragment. This sequence can be used in the method of the invention for determining the susceptibility to activitial drugs of viruses which contain RT genes and are present in a biological sample. It comprises: (1) releasing, isolating or concentrating the polymucleic acids present in a sample; (2) amplifying the relevant part of the RT genes present with at least one suitable primer pair; (3) hybridising the comprises being applied to known locations on a solid support, and are the probes being applied to known locations on a solid support, and are capable of simultaneously hybridising to their respective traspet regions under appropriate hybridisation and wash condition allowing the detection of homologous targets, or with the probes hybridising specifically with a sequence complementary to any of the traget sequence at the codons of interest (codons 38-44, 47-53, 65-72, 73-77, 148-154, 180-187, 122-216, and 217-220), and (4) inferring the nucleotide sequence at the codons of interest and/or the amino acids of the codons of interest and/or antiviral drug resistance spectrum, and possible the type of viral isolates involved from the differential hybridisation signals obtained in step (4). The method is specifically used to detect antiviral drug resistant strains of viruses containing RT genes, especially HIV retroviruses and Hepadnaviridae. The method can also be used for
                                                                          ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Determining susceptibility to antiviral drugs of reverse transcriptase containing viruses - useful for genotyping HIV RT and detecting antiviral

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Human; vascular endothelial growth factor; VEGF; antisense; preparation; oligonucleotide; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Method for preparing an anti-sense nucleic acid - useful for preventing expression of a target gene.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              The present sequence is an oligonuclectide antisense to human vascular endothelial growth factor (hVEGF) cDNA. It was prepared by hybridising several random nuclectide sequences to DNA or RNA encoding a target procein, i.e. hVEGF cDNA, to obtain hybridising antisense
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Human; epidermal growth factor receptor; EGFR; EGF-R; target sequence;

                                                                                                                                                                                                                                                                                                                                                                                                          which specifically cleave RNA derived from an epidermal growth factor receptor (GGF-R) gene. AAV97221 to AAV98043 and AAV98979 to AAV99000 represent specifically claimed target sequence from human EGF-R. AAV98044 to AAV98066 and AAV98067 to V9878 represent hammerhead ribozymes and harbin ribozymes respectively for human EGF-R. The NAMs are useful for cleaving EGF-R RNA in the treatment of a condition associated with EGFR expression levels e.g. to inhibit cell proliferation in the prevention or transment of cancers. The NAMs can also be used as diagnostic tools to examine genetic drift and mutations within diseased cells or to detect the presence of EGF-R RNA in a cell
                                                                                                                                                                                                                                                                                                       Enzymatic nucleic acids - which cleave RNA derived from an epidermal growth factor receptor, useful for inhibiting cell proliferation and for
                                                                                                                                                                                                                                                                                                                                                                                               The present invention describes enzymatic nucleic acid molecules (NAMs)

AAV48709-886 represent antisense oligonucleotides directed against the ExbB-2 gene. Of these, only oligonucleotides AAV48709-91 resulted in Significant redeution in ExbB-2 protein expression, while cigiqual coligonucleotides AAV48792-886 had little effect. The oligonucleotides CC oligonucleotides AAV48792-886 had little effect. The oligonucleotides CC exemplify the invention. The specification describes oligonucleotides that consecutive contain 8-30 mucleotides able to form three H-bonds each to four consecutive mucleotides able to form three H-bonds each to four consecutive cursecutive cytosines; and the ratio between residues able to form two H-bonds each (2R) or three such bonds (3R) is given by 2R/3R = 0.33-0.72. The coligonucleotides are used to modulate expression of genes, particularly the genes for p53, Erb-2, juns, junb, TGF-beta 1 or beta 2 to control proliferation of primary cell cultures (e.g. bone marrow stem, liver or kidney cells, osteoblasts, osteoblasts and/or keratinocytes). The chigonucleotides can also be used to analyse function of proteins (by altering their expression or activity) and therapeutically, e.g. in cases consecuting TGF) for stimulating the immune system
                                                                                                                      Preparation of antisense oligo:nucleotide(s) which lack long runs of consecutive guanosine or inosine - and have specific ratio of residues able to form two or three hydrogen bonds, have greater activity and reduced toxicity, used therapeutically or to modulate growth of cells in
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Human; aryl hydrocarbon nuclear transport; ARNT; TIE-2; angiogenesis; integrin alpha 6 subunit; integrin subunit beta 3; hairpin ribozyme; harmerhead ribozyme; angiogenic factor; cytostatic; antidiabetic; ophthalmologic; antidiamatory; antiarthritic; antipsoriatic; ARNT; dermatological; RNA cleavage; cancer; diabetic retinopathy; arthritis; age related macular degeneration; inflammation; neovascular glaucoma; myopic degeneration; psoriasis; verruca vulgaris; angiofibroma; tuberous sclerosis; pot-wine stain; Sturge Weber syndrome; Rippel-Trenaunay-Weber syndrome; Osler-Weber-Rendu syndrome; ss.

capable of modulating a process in a biological system. The method capable of modulating a process in a biological system. The method capable of modulating a process in a biological system. The method comprises: (a) introducing into the system a random library of nucleic acid catalysts (NAC) having a substrate binding domain (SBD), comprising a random sequence, and a catalytic domain (CD); and (b) identifying NAC in systems where modulation has occurred and/or determining the sequence of at least part of the SBDs in such systems. Nucleic acid molecules with end catalytic activity, from the present invention, are used to modulate gene expression in plant and mammalian cells and to cleave target nucleic acid, particularly for treating systemic diseases cleave target nucleic acid, particularly for treating systemic diseases caused by specific RNA, e.g. cancer, inflammation, psoriasis, non-hepatic acid, particularly for med to treat cancer, restenosis, psoriasis or rheumatoid arthritis, or used to treat cancer, restenosis, psoriasis or rheumatoid arthritis, or generally any condition associated with the level of c-raf. Introduction cell sugar/phosphate modifications increases stability against nuclease and activity. ANY90922 to AAV93877 repersent NACs that can be used in the method, specifically for modulating the expression of a Raf gene
Novel ribozymes for modulating the synthesis, expression and/or stability of an mRNA encoding an angiogenic factors.
                                                                                                                                                                                                                                                                                                                                                                                                                                                            integrin subunit alpha-6, or integrin subunit beta-3

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        ઠે
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   capable of modulating a process in a biological system. The method capable of modulating a process in a biological system. The method capable of modulating a process in a biological system. The method comprises: (a) introducing into the system a random library of nucleic acid catalysts (NAC) having a substrate binding domain (BBD), comprising a random sequence, and a catalytic domain (CD); and (b) identifying NAC in systems where modulation has occurred and/or determining the sequence of at least part of the SBDs in such systems. Nucleic acid molecules with endonucleas activity and catalytic activity, from the present invention, are used to modulate gene expression in plant and mammalian cells and to cleave target nucleic acid, particularly for treating systemic diseases caused by specific RNA, eg. cancer, inflammation, psoriasis, non-hepatic ascites and infection. They may also be used to detect genetic drift and mutching in diseased cells and to determine craft RNA. Specifically NACs with RNA-cleaving activity that modulate expression of the Raf gene, are used to treat cancer, restencsis, psoriasis or rheumatoid arthritis, or generally any condition associated with the level of c-raf. Introduction of sugar/phosphate modulations increases stability against nuclease and activity. AAV90922 to AAV909377 represent NACs that can be used in the cativity. AAV90922 to Racking the expression of a Raf gene
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Triplex formation; DNA detection; triple helix; identification; bacteria;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Identifying new catalytic nucleic acid that modulates selected processes - especially ribozymes that cleave Raf RNA for treating cancer, restenceis, and also new ribozymes and modified nucleoside triphosphates used as antiviral agents and synthons.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Triple helix third strand of 23S rRNA gene nucleotides 471-484.

The present sequence represents a polymuclectide that is able to form a triple helix with a double stranded sequence. Cytosine bases in the present can be replaced with 5-methylcytosine for increased triplex tability. The present sequence is used in the assay of the invention, where it can be part of the anchor DNA or reporter DNA sequence. The assay comprises adding a sample containing double-stranded DNA test sequences to an aqueous medium containing at least one complex of anchor DNA, attached to a solid support, and reporter DNA, where either a part of the anchor DNA or reporter DNA, where either a part of the anchor DNA test sequence. Triples form a triple-strand structure with part of the test sequence. Triplex formation results in displacement of the reporter DNA which is detected as an indication of the presence of the DNA test sequence. The method is used to detect DNA genes for ribosomal RNA) in clinical samples, but also detecting concepenes and Hepatitis B virus
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Bnzymatic nucleic acid; hammerhead ribozyme; virus replication; cleavage;

enzymatic nucleic acid, especially a hairpin ribozyme, which cleaves the Hepatitist C virus (HCV) RNA sequence at the base position given in the descriptor line. The HCV sequence was screened for optimal ribozyme target sites using a computer folding algorithm and regions of the mRNA which did not form secondary folding algorithm and regions of the mRNA which did not form secondary folding structures and contained potential ribozyme cleavage sites were identified. Ribozymes were synthesised to larget these sites and their activities optimised by either varying the length of the binding arms or by modification to prevent degradation by nucleases. The ribozymes of the invention inhibit gene expression and/or viral replication, and are used to treat diseases associated with Hepatitis C virus (HCV) infection, e.g. cirrhosis, liver failure and hepatocellular carcinoma. The ribozymes may be used in combination with difference of the complication, other infectious diseases, autoimmune
                                                                                                                                                                                                                                                                    Novel ribozymes for the treatment of diseases and conditions related to hepatitis C infection.
                                                                                                                                                                                                                                                                                                                                                                              The present sequence represents the preferred target sequence of

uncleic acid (A') that modulates expression of the oestrogen receptor concline, are used to treat cancer (particularly of breast or endometrium), in vivo or by transforming cells ex vivo and implanting treated cells, or on vivo or by transforming cells ex vivo and implanting treated cells, or in vivo or by transforming cells ex vivo and implanting treated cells, or or other conditions associated with levels of cestrogen receptor.

CC for other conditions associated with levels of cestrogen receptor.

CC Secause of the high selectivity for targeted MNA, (A) can also be used to correlate inhibition of gene expression with alterations in phenotype, correlate inhibition of gene expression with alterations in phenotype, correlate inhibition of gene expression with alterations in phenotype, correlate inhibition of gene expression with alterations in phenotype, correlate inhibition of gene expression with alterations in phenotype, corresponding to modifications in (A) improves used with DNA). The combination of modifications in (A) improves the sequences, and AAA2593 represent their corresponding target sequences, and AAA2592 represent their corresponding target sequences, and AAA2610 to AAA2621 to AAA2621 to AAA2621 to AAA2621 to Expresent other ribozyme sequences and continued and continu New nucleic acids that interact, and optionally cleave, target sequences, The present invention describes nucleic acids (A) that interact stably least one phosphoro(di)thioate Bellon L; Karpeisky A, Haeberli P; Mcswiggen JA, is T, Woolf T, with a target sequence and contain at Claim 79; Page 98; 148pp; English. Beigelman L, Mcswig Zwick M, Jarvis T, used to treat cancer. WPI; 2000-013248/01 Thompson JD, Beig Reynolds M, Zwick Matulic-Adamic J;

```
with a target sequence and contain at least one phosphoroidilythicate
link, having endonuclease activity. (A), and more generally any catalytic
nucleic acid (A) that modulates expression of the cestrogen receptor
gene, are used to treat cancer (particularly of breast or endometrium),
in vivo or by transforming cells ax vivo and implanting treated cells, or
for other conditions associated with levels of cestrogen receptor.
Because of the high selectivity for targeted RNA, (A) can also be used to
correlate inhibition of gene expression with alterations in phenotype,
correlate inhibition of gene expression with alterations in phenotype,
correlate inhibition of gene expression with alterations in phenotype,
correlate inhibition of gene expression with alterations in phenotype,
correlate inhibition of gene expression with alterations in phenotype,
correlate inhibition of gene expression with alterations in phenotype,
correlate inhibition of gene expression with alterations in phenotype,
correlate inhibition of gene expression with alterations in phenotype,
correlate inhibition of gene expression with alterations in phenotype,
correlate inhibition of gene expression with alterations in phenotype,
correlate inhibition of gene expression of modifications in (A) improves
correlate inhibition of same way that restriction endomucleases are
corresponded to AAA22692 represent their corresponding target
correlate inhibition of AAA26212 represent their corresponding target
correlate inhibition of AAA26212 represent their corresponding target
antisense oligonucleotides used in the exemplification of the present
                                                                              New nucleic acids that interact, and optionally cleave, target sequences, used to treat cancer.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Infection; antisense RNA; ribozyme; DNAzyme; antiviral; gene therapy; papilloma virus; hepatitis. This invention relates to oligonucleotides used for cleaving, detecting and amplifying the mecA gene (associated with methicillin resistance in Staphylococcus aureus) or its derived RNA. The invention also comprises a detection method employing an RNA amplification process, using RNA certification process in the presence of a complementary oligonucleotide probabelled with an intercalated fluorescent dye, where complementary binding of the probe to the RNA transcription product results in a change of the probe to the RNA transcription product results in a change of the probe to the RNA transcription product results in a change of the probe to the RNA transcription product results in a change of the probes, for the relative to that of a situation where a complex formation is absent, and then measuring the fluorescence complex for detection and then measuring the fluorescence of intensity of the reaction solution. The oligonucleotides may be used as primers or probes, for detecting methicillin-resistant S. aureus in clinical samples. They may also be used therapeutically to inhibit RNA reverse transcription or translation. These oligonucleotides permit rapid and very sensitive detection/identification of the mecA gene, at a call very sensitive detection/identification of the mecA gene, at a call very sensitive detection/identification of the mecA gene, at a call very sensitive detection/identification of the mecA gene, at a call very sensitive detection/identification of the mecA gene, at a call very sensitive detection/identification of the mecA gene, at a call very sensitive detection/identification of the mecA gene, at a call very sensitive detection/identification of the mecA gene, at a call very sensitive detection/identification of the metA denaturation of target RNA. The present sequence represents a methicillin resistant
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        New oligonucleotide specific for the mecA methicillin-resistance gene, useful for cleavage, detection and amplification of the gene or related
invention are useful for determining the expressed amount of E2F or the transcription activity of E2F. The present sequence represents an E2F detection oligonuclectide of the invention
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Methicillin resistant Staphylococcus Aureus; MRSA; primer; ss; mecA;

and amplifying the mech gene (associated with methicillin resistance in staphylococcus aureus) or its derived MNA. The invention also comprises a detection method employing an RNA amplification process, using RNA detection method for method process, using RNA methicillin-resistance in derived from the mech gene as template. Also disclosed is a detection method for a methicillin-resistant S. aureus (MRSA), comprising an RNA method for a methicillin-resistant S. aureus (MRSA), comprising an RNA method for a methicillin-resistant S. aureus (MRSA), comprising an RNA complex labelled with an intercalated fluorescent dye, where complementary binding of the probe to the RNA transcription product results in a change of the probes to the PRNA transcription product results in a change in the fluorescent property relative to that of a situation where a complex formation is absent, and then measuring the fluorescence intensity of the reaction solution. The oligonucleotides may be used as primers or probes, for detecting methicillin-resistants S. aureus in creverse transcription or translation. These oligonucleotides permit rapid and very sensitive detection/identification of the measuration of the measuration of transcription or translation. These oligonucleotides permit rapid and very sensitive detection/identification of the measuration of transcription or translation. These oligonucleotides permit rapid rarget RNA. The present sequence represents a methicillin resistant
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            ô

The present invention describes a method for detecting mutations associated with anti-HIV drug resistance in a patient by detecting at least cone of the mutations K103N/R, V106A/IL, V181C/I, M184V/I, V186E, C190A/S/R, T215Y/F/D/S/A and/or O151M/L in the reverse transcriptase (RT) of 190A/S/R, T215Y/F/D/S/A and/or O151M/L in the reverse transcriptase (RT) of HIV strains in a biological sample using a specific set of probes of the formal set of method and the nucleic acid sequences used in the method are useful for determining viral mutations and/or polymorphisms in the HIV RT gene associated with resistance. The probes are useful for the genetic detection, preferably in virco detection of the mutations K103N/R, V106A/J/L, Y181C/I, O151M/L, M184V/I, Y188L, G190A/S/R and/or C715Y/F/D/S/A in the RT of HIV strains in a biological sample, where the mutation is associated with anti-HIV drug resistance. The method provides a rapid, reliable and precise assay or determination and monitoring of antiviral drug resistance or mutation is associated with anti-HIV drug resistance of antiviral drug resistance or mutations associated with drug resistance of sequences and probes which are used in the exemplification of the present invention. Detecting mutations associated with anti-HIV drug resistance comprises detecting at least one of the mutations in the HIV reverse transcriptase gene by using probes optimized to function together in a reverse-hybridization assay.

The present invention describes a method for detecting mutations associated with anti-HIV drug resistance in a patient by detecting at associated with anti-HIV drug resistance in a patient by detecting at least one of the mutations KlOSN/R, VIOSA/IV, VISIC/I, MIS4V/I, VISEL, CG190A/S/R, T21SY/F/D/S/A and/or CILSM/L in the reverse transcriptase (RT) of HIV strains in a biological sample using a specific set of probes coptimised to function rogether in a reverse-hybridisation assay. The competence and the nucleic acid sequences used in the method are useful for determining viral mutations and/or polymorphisms in the HIV RT gene cascolated with resistance. The probes are useful for the genetic detection, preferably in vitro detection of the mutations K103N/R, CC 7215Y/F/D/S/A in the RT of HIV strains in a biological sample, where the mutation is associated with anti-HIV drug resistance. The method provides a rapid, reliable and precise assay or determination and monitoring of a rapid, reliable and precise assay or determination and monitoring of a rapid, reliable and precise assay or determination and monitoring of a rapid, reliable and precise assay or determination and monitoring of viruses containing RT genes . RAZ34642 represent HIV RT sequence and probes which are used in the exemplification of the present
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Detecting mutations associated with anti-HIV drug resistance comprises detecting at least one of the mutations in the HIV reverse transcriptase gene by using probes optimized to function together in a reverse-hybridization assay.
                                                                                                                                           Human immunodeficiency virus; HIV; reverse transcriptase; RT; enzyme; detection; mutation; anti-HIV drug resistance; polymorphism; resistance;

The present invention relates to enzymatic nucleic acids which specifically cleave RNA derived from Hepatitis C virus (HCV). The enzymatic nucleic acid or inbozyme is in a harmerhead (HH). The carginal control of the substrate sequences defined in the specification. The HCV is controlled for modulating the expression and/or replication of HCV. They can be used to treat circhosis, liver failure and/or hepatocellular carcinoma. The HCV ribozymes are also useful for treating a condition associated with HCV infection in conjunction with one or more other drug therapies, particularly type I interferon. The present sequence represents a substrate for a HCV hairpin (HP) ribozyme. Note: Some of the sequence data for this patent did not form part of the printed specification. The complete sequence data for this patent was contained in electronic format directly from the USPTO web site at
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          New ribozymes targeting RNA derived from hepatitis C virus inhibit viral replication and are useful to treat hepatitis C virus infections and cirrhosis, liver failure or hepatocellular carcinoma.
                                                                                                                       Enzymatic nucleic acid, RNA cleavage, Hepatitis C virus infection, HCV ribozyme, HCV expression, HCV replication, cirrhosis, virucide, liver failure, hepatocellular carcinoma, HCV infection, drug therapy, type I interferon, interferon alpha, interferon beta, cytostatic, interferon gamma, consensus interferon, hepatotropic, antiinflammatory, substrate, hairpin ribozyme, HP ribozyme, se.
                                                                                      Hepatitis C virus substrate #24 for HCV hairpin ribozyme #24.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       ä
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Macejack
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Sequence 14 BP; 3 A; 5 C; 2 G; 0 T; 4 U; 0 Other;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Slatt L, Mcswiggen JA, Roberts B, Pavco PA,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     segdata.uspto.gov/psipsDIDEntry.html

The PNA probes are useful for detecting, identifying and/or quantifying Candida yeast in clinical samples, food, beverages, water, dairy products or environmental samples, personal care products, pharmaceutical products, for analysing or detecting the presence of a nucleic acid within an organism, or for the analysis of organisms or a nucleic acid extracted from or derived from an organism of interest. The present sequence is a probing nucleobase sequence of PNA probe specific for Candida glabrata. This sequence is used for detection of Candida yeast

                                                                                                                                                                                                                                                                                                                                    The present invention relates to High Bone Mass (HBM), LRP5 (Zmax1) and the formulants, which results in a HBM-like phenotype when expressed in a cell. The HBM-like phenotype results in bone mass modulation and/or lipid level modulation. The invention is useful for diagnosing a HBM-like phenotype in a subject and for preparing a composition for modulating bone mass and/or lipid levels in a subject suffering from e.g. setellight state the invention.

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleoride, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders, see AAF45151 and AAF45153- (chthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, inchipasis, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain growth factor—mediated malignancies, other sclerotic chisease, kidney disease, hyperproliferation of the inside of blood vessels or any other hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Antisense therapy; antiproliferative; antiinflammatory; antipsoriatic; cytostatic; dermatological; cardiant; virucide; ophthalmological; keloid; skin discorder; insulin-like Growth Factor 1 receptor; IGF-1; pityriasis; IGF binding protein; IGFBP-2; IGFBP3; inflammation; psoriasis; pilatis; growth factor mediated cell proliferation; ichhyosis; serborrhoea; ruba; keratosis; neoplasia; scleroderme; wart; skin cancer; sclerotic disease; hyperneovascular condition; hyperplasis, kidney disease;
                                                                                                                                                                                                                                                                                              Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or

```
The present invention relates to a method for ameliorating the effects of antisense oligonucleotide, (for Insulin-like Growth Factor [IGF] receptor, IGF binding protein [IGFBP]-2 or ISFBP3, which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAP45151 and AAF45153-019gonucleotides of the present invention (see AAP45151 and AAF45153-P45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovasular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other selerotic disease, kidney disease, hyperproliferation of the inside of blood
                                                                                                                 Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Selection of low frequency antigen-specific B lymphocytes - using antigen

The sequences given in AAQ48499-514 are primers which amplify human heavy corresponding segments almost 100% of the time in single cells taken from the human lymphoblastoid 100% of the time in single cells taken from the human lymphoblastoid 100% of the time in single cells taken from first five amino acids of the mature immunoglobulins and cover the known sequences from single B cells is amplified by semi-nested PCR. The sequences from single B cells is amplified by semi-nested PCR. The procedure calls for two rounds of PCR amplification. The same sets of degenerate 5' VM and VM primers are used for both rounds of PCR, whereas the 3' primers used in the second round of PCR are derived from the insert of internal region towards the 3'-end of the DNA fragments amplified in the first round. Therefore in the second round of PCR the 5' end is not nested but the 3'-end is. The VM and VL gene segments amplified by this method may be cloned and sequenced by incorporating them into an field.)
                                                                                                                                                                                                                                                                                                                                                                                                     Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      RNA; enzyme; enzymatic RNA molecule; ERM; cleave; RNA; mRNA; HDRNA; picornavirus; HIV; immunodeficiency virus; hepatitis B virus; HBV; papilloma virus; HBV; Epstein-Barr virus; BBV; TCIV; T-Cell leukaemia virus; hepatitis C virus; HCV; cytomegalovirus; influenza virus; HSV; heppes simplex virus; vector; immune response; antibody; ribozyme; viral RNA; treatment; ss.

The sequences (AAQ52824-Q52890) are pref. Cytomegalovirus target sequences for enzymatic RNA molecules. The RNA molecules are complementary to a substrate binding region in the specified gene target. They also have enzymatic activity, in that they specifically cleave RNA in the target. The ERMS interfere with viral replication and therefore have anti-viral properties. They can be used to attenuate viruses to be used in vaccines. (Updated on 25-MAR-2003 to correct PN field.) (Updated on 25-MAR-2003 to correct PR field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                        \mathtt{Enzymatic} \mathtt{RNA} molecules - used to inhibit viral replication, infection and gene expression.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 ô
                                                                                                                                                                                                                                                                                                                                The sequences (AAQ52824-Q52890) are pref. Cytomegalovirus target sequences for enzymatic RNA molecules. The RNA molecules are complementary to a substrate binding region in the specified gene target. They also have enzymatic activity, in that they specifically cleave RNA in the target. The ERMs interfere with viral replication and therefore have anti-viral properties. They can be used to attendate viruses to be used in vaccines. (Updated on 25-MAR-2003 to correct PN field.) (Updated on 25-MAR-2003 to correct PR field.) (Updated on 25-MAR-2003 to correct PR field.)

Selecting antigen-specific B lymphocytes - by fluorescence activated cell
                                                                                                                                                                                                                                                                                                                                                                  The sequences given in AAO61825-50 and AAO61886-906 are oligonucleotides which contain a G4 or two G3 stretches and which may be used for inhibiting replication of herpes simplex virus (HSV). Oligonucleotides such as these may also be used for inhibiting activity of HIV, human cytomegalovirus or influenza virus, or for treating inflammatory and neurological disorders caused by phospholipase A2 activity in cases of hyperproliferation, malignancy, cardiovascular disease and snake bite. They may also be used for inhibiting division of malignant cells by modualting telomere length, which may also retard aging. (Updated on 25-MAR-2003 to correct PN field.)
                                                                                                                                                                                                                                                  New modified oligo-nucleotide contg guanine quartet - inhibits activity of viruses, e.g. HIV, and phospholipase A2 and modulates telomere length of chromosomes.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Primer, amplification; Vh; heavy chain, antibody; B cells; lymphocyte; immunoglobulin; PCR; polymerase chain reaction; ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              0
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            The sequences given in AAQ73325-81 represent oligonucleotides which hybridise specifically with DNA or RNA from a herpes virus gene corresponding to one of the open reading frames UI5, -8, -9, -50, -27, -30, -42, -52 or 18175 of herpes simplex virus type I (HSV-1). These oligos pref. hybridise with a translation initiation site, a coding region or a 5' untranslated region. These oligos may be used in compositions for the treatment and diagnosis of herpes viral infection, by contecting the virus or the animal, or its cells, tissues or body fluids with the oligo. (Updated on 25-MAR-2003 to correct PN field.)
                                                                                                                                                                                                                                                                                                                                                                                                New oligonucleotide(s) hybridising with DNA or RNA of herpesvirus gene are used in the treatment and diagnosis of herpes simplex virus, cytomegalovirus, Epstein Barr virus and varicella zoster infections.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Inhibition, replication, herpes simplex virus, HSV, HIV, human cytomegalovirus; influenza virus, influenzation neurological disorders, phospholipase A2 activity, hyperproliferation, malignancy, cardiovascular disease, snake bite; malignancy;

                                                             This oligonucleotide is suitable to be used as a 5' end primer for human who chain coding segments. The preferred set of 5' end primers for Wh consists of 5 degenerate groups of oligonucleotides and one nondegenerate oligonucleotide (AAQ68539-44), totaling 53 sequences. This set of primers corresponds to the first 5 amino acids of the mature immunoslobulins and sequenced. The variations in this sequence which yield these other sequenced. The variations in this sequence which yield these other oligonucleotides are that the first quantidine uncleotide can be a cytosine, the sixth guanidine can be a thymidine and the thirteenth guanidine can be a thymidine do correct PF
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     fibrosis gene. The primers are designed to be complementary to eight of the most common mutations within the CP gene. Detection is carried out by the incorporation of a labelled dideoxynucleotide. Individuals carrying the mutation incorporate a different base as opposed to normal individuals. This primer detects the delta-507 mutation site by the incorporation of dadTP as opposed to ddGTP. (Updated on 25-MAR-2003 to correct PN field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           The primers (AAQ55452-62) are use to detect mutations within the cystic
                                                                                                                                                                                                                                                                     Gaps
sorting using at least 2 different antigen probes with fluoro:chrome
labels.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 The sequence is an antisense molecule directed against position +4 to +18, relative to the start codon of the gene for mouse fibroblast growth factor 1. The polymucleotide can be used for inhibiting vascular smooth muscle cell proliferation and for treating a disease e.g. vascular stenosis, post angioplasty restenosis, atherectomy, atherosclerosis, attain venous shunt failure, cardiac hypertrophy, vascular surgery and organ transplant. See also AAQ70333-60. (Updated on 25-MAR-2003 to correct PN field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          New anti-sense polynucleotide(s) to fibroblast growth factor receptor used for inhibiting vascular smooth muscle cell proliferation, partic. for treating restenosis.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Gaps

 Oligonucleotides (AAQ81716-20) are antisense oligonucleotides complementary to the mRNA of the fibrogenic cytokine tumour necrosis factor-alpha (Thr-alpha) which inhibit expression of this cytokine. The oligonucleotides may contain phosphorothicate linkages to render the nuclease resistant. They are used to inhibit scar formation at a wound site by preventing the production of fibrogenic cytokines such as transforming growth factor-beta (Tepbeta), Thr-alpha, platelet derived growth factor (PDGF), fibroblast or epithelial growth factors (FGF or at the wound periphery. The oligonucleotides reduce collagen content of the wound and increase tensile strength. Treated wounds are indicatinguishable from normal tissue. (Updated on 25-MAR-2003 to correct
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     New anti-sense oligo-nucleotide(s) to mRNA of fibrogenic cytokine - esp. transforming growth factor-beta and platelet derived growth factor, used topically to inhibit scar formation at wound sites.

```
The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves mRNA coding for a protein of respiratory syncytial virus (RSV) at the nucleotide base postition indicated in the DE line. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Chowrira B, Direnzo A, Draper KG, Dudycz LW; isky A, Kisich K, Matulic-Adamic J, Mcswiggen JA; P, Beigleman L, Shllivan SM, Sweedler D, Thompson JD; N, Wincott FE, Woolf T;

The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves ICAM-1 mRNA at the nucleotideb base position indicated in the DE line. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes cleave the ICAM-1 target sequences and thereby inhibit ICAM-1 expression, making them useful for reducing transplant refjection and alleviating symptoms in patients with rheumatoid arthritis, asthma and other inflammatory disorders. (Updated on 25-WAR-2003 to correct PI field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Bnzymatic nucleic acid; ribozyme; trans cleavage; inhibition; gene expression; downregulation; interleukin-5; IL-5; ICAM-1; intercellular adhesion molecule; rel A; tumour necrosis factor; TNF-alpha; respiratory syncytial virus; RS; bcr-abl; oncogene; translocation; chronic myelogenous leukaemia; CML; cancer; Philadelphia chromosome; inflammation; autoimmune disease; atheroselerosis; myoardial infarction; stroke; restenosis; transplant rejection; rheumatoid arthritis; psoriasis; myocardial; Kawasaki disease; septic shock; HIV; human immunodeficiency virus; acquired immune deficiency syndrome; AIDS;

RSV 1C hammerhead ribozyme target sequence (nt. position 163)

(revised)
(first entry)

25-MAR-2003 24-APR-1997

```
The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves relA mRNA at the nuclectide base position indicated in the DE line. The relA gene product is a subunit of the transcriptional regulator NF-kappaB and is implicated specifically in the induction of inflammatory responses. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes are designed to cleave the target cusful for treating rheumatoid arthritis, restenosis and asthma as well as for increasing tolerance to transplanted tissues. The potentially immunosuppressive properties of a ribozyme that cleaves relA mRNA means that uses are limited to local delivery, acute indications or ex vivo
                                                                                                                                                                                                                                                                                                                                                                                                           Stinchcomb DT, Chowrira B, Direnzo A, Draper KG, Dudycz LW; Stinch S, Karpelsky A, Kisich K, Matulic-Adamic J, Mcswiggen JA; Modak A, Pavco P, Beigleman L, Sullivan SM, Sweedler D, Thompson JD; Tracz D, Usman N, Wincott FE, Woolf T;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves mRNA coding for a protein of respiratory syncytial virus (RSV) at the nucleotide base position indicated in the DE line. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Ribozymes having modified bases and methods for producing them - for in inhibiting disease related genes.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Claim 2; Page 269; 407pp; English.

Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes cleave the target sequences and can be used for treatment and diagnosis of RSV infection. (Updated on 25-MAR-2003 to correct PI field.) (Updated on 27-AUG-2003 to correct PI

 The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves relA mRNA at the nucleotide base position indicated in the DE line. The relA gene product is a subunit of the transcriptional regulator NF-kappaB and is implicated specifically in the induction of inflammatory responses. Regions of the mRNA that do not form secondary folding structures and that contain operations of the premise and harmerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes are designed to cleave the target sequences and thereby inhibit relA expression, making them potentially useful for treating rheumatoid arthritis, restenosis and asthma as well as for increasing tolerance to transplanced tissues. The pocential as for increasing tolerance to transplance that cleaves relA mRNA means that uses are limited to local delivery, acute indications or ex vivo treatment. (Updated on 25-MAR-2003 to correct PI field.)
                                                                                                                                                                                                                                                                                                                                                    o DT, Chowrira B, Direnzo A, Draper KG, Dudycz LW;

Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and
                                                                                                                                                                                                                                                                                                                                                                                                                                      Ribozymes having modified bases and methods for producing them - for use in inhibiting disease related genes.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Claim 2; Page 276; 407pp; English.

synthesised with modifications that improve their nuclease resistance. The riboxymes cleave the target sequences and can be used for treatment and diagnosis of RSV infection. (Updated on 25-MAR-2003 to correct PI field.) (Updated on 27-AUG-2003 to correct OS field.)

Regions of the mNAA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these manks sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes cleave the ICAM-1 target sequences and thereby inhibit ICAM-1 expression, making them useful for reducing transplant rejection and alleviating symptoms in patients with rheumacoid arthritis, asthma and other inflammatory disorders. (Updated on 25-MAR-2003 to correct PI field.)

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The present sequence represents a preferred target sequence for an enzymatic nucleic acid (1.e. a ribozyme) which Oleaves mRNA coding for a protein of respiratory syncytial virus (RSV) at the nucleotide base position indicated in the DE line. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairplin ribozyme claevage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes claeve the target sequences and can be used for treatment and diagnosis of RSV infection. (Updated on 25-MAR-2003 to correct PI field.) (Updated on 27-AUG-2003 to correct PI
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Claim 2; Page 269; 407pp; English.

Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes cleave the ICAM-1 target sequences and thereby inhibit ICAM-1 expression, making them useful for reducing transplant arejection and alleviating symptoms in patients with rheumatoid arthritis, asthma and other inflammatory disorders. (Updated on 25-MAR-2003 to correct PI field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Stinchcomb DT, Chowrira B, Direnzo A, Draper KG, Dudycz LW; Grimm S, Karpelsky A, Kisich K, Matulic-Adamic J, Mcswiggen JA; Modak A, Pavco P, Balglemen L, Sullivan SM, Sweedler D, Thompson JD; Tracz D, Usman N, Wincott FE, Woolf T;

```
The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves relA mRNA at the nucleotide base position indicated in the DE line. The relA gene product is a subunit of the transcriptional regulator NF-KappaB and is implicated specifically in the induction of inflammatory responses. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes are designed to cleave the target sequences and thereby inhibit relA expression, making them potentially useful for treating rheumatoid arthritis, restenosis and asthma as well as for increasing tolerance to transplanted tissues. The potential communosuppressive properties of a ribozyme that cleaves relA mRNA means that uses are limited to local delivery, acute indications or ex vivo treatment. (Updated on 25-MAR-2003 to correct PI field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Enzymatic nucleic acid, ribozyme, trans cleavage, inhibition; gene expression; downregulation; interleukin-5; IL-5; ICAM-1; intercellular adhesion molecule; rel A; tumour necrosis factor; TNF-alpa, respiratory syncytial virus; RSV; bcr-abl; oncogene; translocation; chronic myelogenous leukaemia (ML; cancer; Philadelphia chromosome; inflammation; autoimmune disease; ransplant chromosome; inflammation; stroke; restenosis; transplant rejection; rheumatoid arthritis; psoriasis; myocardial infarction; attoke; restenosis; myocardial; Kawasaki disease; septic shock; HIV; human immunodeficiency virus; acquired immune deficiency syndrome; AIDS;

The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves mRNA coding for a protein of respiratory sproytial virus (RSV) at the nucleotide base position indicated in the DE line. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                b DT, Chowrira B, Direnzo A, Draper KG, Dudycz LW;

Modak A,
Tracz D,
  The present sequence represents a preferred target sequence for an environmental much at the mucleotide base position indicated in the DE line. The relA gene product is a subunit of the transcriptional regulator NF-kappaB and is implicated specifically in the induction of inflammatory responses. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences of prompter analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes are designed to cleave the target sequences and thereby inhibit relA expression, making them potentially useful for treating rheumatoid arthritis, restenosis and aschma as well as for increasing tolerance to transplanted tissues. The potential inmunouppressive properties of a ribozyme that cleaves relA mRNA means that uses are limited to local delivery, acute indications or ex vivo
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            ó

The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves ICAM-1 mRNA at the nucleotide base position indicated in the DE line. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes cleave the ICAM-1 target sequences and thereby inhibit ICAM-1 expression, making them useful for reducing transplant arejection and alleviating symptoms in patients with rheumatoid arthritis, asthma and other inflammatory disorders. (Updated on 25-WAR-2003 to correct PI field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Enkymatic nucleic acid; ribozyme; trans cleavage; inhibition; gene expression; downregulation; interleukin-5; IL-5; ICAM-1; intercellular adhesion molecule; rel A; tumour necrosis factor; TNF-alpha; respiratory syncytial virus; RV, bcr-ab; oncogene; translocation; dironic myelogenous leukaemia; CML; cancer; Philadelphia chromosome; inflammation; autoimmune disease; transplant rejection; rheumatoid arthritis; psoriasis; myocardial infarction; stroke; restenosis; transplant rejection; rheumatoid arthritis; psoriasis; myocardial; Kawasaki disease; septic shock; HIV; human immunodeficiency virus; acquired immune deficiency syndrome; AIDS;

                                                                                                                                                                                                    Mus musculus.
                                                                                                                                                                                                                               WO9523225-A2.
The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves relA mRNA at the nucleotide base position indicated in the DE line. The relA gene product is a subunit of the transcriptional regulator NF-kappaB and is implicated specifically in the induction of inflammatory responses. Regions of the mRNA that do not form secondary folding structures and that contain product analysis. Ribozymes directed against these mRNA sequences were designed and halrpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their sequences and thereby inhibit relA expression, making them potentially useful for treating rheumatoid arthritis, restenosis and asthma as well as for increasing tolerance to transplanted tissues. The pocential infinuence properties of a ribozyme that cleaves relA mRNA means that uses are limited to local delivery, acute indications or ex vivo treatment. (Updated on 25-WAR-2003 to correct PI field.)
                                                                                                                                                                                                                                                                                                                                     b DT, Chowrira B, Direnzo A, Draper KG, Dudycz LW;

The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves ICAM-1 mRNA at the nucleotide base position indicated in the DE line. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozymes cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes cleave the ICAM-1 target sequences and thereby inhibit ICAM-1 expression, making them useful for reducing transplant
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    b DT, Chowrira B, Direnzo A, Draper KG, Dudycz LW;

Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes are designed to cleave the target sequences and thereby inhibit TNF-alpha expression, making them potentially useful for treating rheumatoid arthritis, septic shock and other inflammatory disorders including psoriasis, as well as for treatment of AlbS. (Updated on 25-MAR-2003 to correct PI field.)

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          The present sequence represents a preferred target sequence for an enzymatic nucleic acid (i.e. a ribozyme) which cleaves mRNA coding for a protein of respiratory syncytial virus (RSV) at the nucleotide base position indicated in the DE line. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes cleave the target sequences and can be used for treatment and diagnosis of EVV infection. (Updated on 25-MAR-2003 to correct PI field.) (Updated on 27-AUG-2003 to correct OS field.)

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         The present sequence represents a preferred target sequence for an the present sequence represents a ribozyme) which cleaves TNF-alpha mRNA at the nucleotide base position indicated in the DE line. Regions of the mRNA that do not form secondary folding structures and that contain potential hammerhead and hairpin ribozyme cleavage sites were identified by computer analysis. Ribozymes directed against these mRNA sequences were designed and synthesised with modifications that improve their nuclease resistance. The ribozymes are designed to cleave the target sequences and thereby inhibit TNF-alpha expression, making them potentially useful for treating rheumatorid arthritis, septic shock and other inflammatory disorders including psoriasis, as well as for treatment of AIDS. (Updated on 25-MAR-2003 to correct PI field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Ribozymes having modified bases and methods for producing them - for use in inhibiting disease related genes.

Sequence 15

```
This sequence represents a polynucleotide which forms part of a peptide nucleic acid (PRA) molecule of the invention. The invention relates to compounds comprising a PNA strand including at least one PNA unit having a pyramidine heterocyclic base which is a C-pyrimidine heterocyclic base. The jivention also relates to compounds which optionally consist of multiple strands for increased binding affinity. The compounds (designated PNA or bis PNA compounds) can bind to complementary nucleic acids with higher affinity and specificity than corresponding polynucleotides and are resistant to degradation by enzymes. They can be used for gene modulation, e.g. as gene targeted drugs for treating diseases such as cancer, viral infections or genetic diseases. They can also be used for research and in diagnostics for detection and isolation of specific nucleic acid sequences and as bitchhology and research probes, primers or artificial restriction curanded DNA, restriction enzyme sites, transcription inhibition.
                                                             ö
                                                                                                                                                                                                                                                                                                                           Peptide nucleic acid, PNA, c-pyrimidine heterocyclic base, cancer, iso-pyrimidine heterocyclic base, increased binding affinity, treatment, degradation resistant, gene modulation, viral infection, ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       New peptide nucleic acid cpds - having C-pyrimidine or iso-pyrimidine heterocyclic base substitutions and opt multiple strands for increased binding affinity.

The present sequence is the peptide nucleic acid (PNA) oligomer ISIS 8129, which specifically binds 1 strand of the NFKappaB transcription factor (TF) binding site on a double stranded DNA in an anti-parallel orientation, and displaces the 2nd strand of the double stranded DNA to inhibit the binding of NFKappaB to its binding site. As the PNA can inhibit the transcriptional activation of a gene, it can be used to treat diseases associated with TF mediated gene expression, e.g. inflammatory disease, ALDS, TF mediated cancer, atherosclerosis, Down's syndrome, Alzheimer's disease, amyotrophic lateral sclerosis and parkinson's disease. The PNA can also be use to identify TF associated with certain disease states. Specifically ISIS 8129 and its parallel binding partner ISIS 9151 bind a single copy of the target with high affinity to form a

                                                                                                                                                     d
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   The present invention describes a novel enzymatic nucleic acid (ENA) having a hammerhead motif (HM) comprising; (i) at least 5 tibose residues (i); (ii) a 2.C-allyl modification at position 4 of the ENA; (iii) at least ten 2.-O-methyl modification, and (iv) a 3'-end modification. The ENA's can inhibit collagenase and stromelysin production in the synovial membrane of joints for the treatment or prevention of arthritis. The ENA's can also be used to treat antigen presenting calls of a donor to induce tolerance be used to treating arthritis. The ENA's can also be used to treat antigen presenting calls of a donor to induce tolerance endeating acid to the containing of a donor. They can also be used for treating allergies and other inflammatory conditions. The ENA's can also treating allergies and other inflammatory conditions. The ENA's can also be used in diagnosis. Ribozyme therapy impacts on the expression of stromelysin without introducing the non-specific effects upon gene expression which accompany treatment with retinoids and dexamethasone.

The ENA's can inhibit collagenase and stromelylain production in the synovial membrane of joints for the treatment or prevention of arthritis, particularly osteoarthritis or rheumatoid arthritis. The ENA's can also
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Arthritic condition; graft tolerance; immune response; target; cleavage; hammerhead ribozyme; hairpin ribozyme; human; rabbit; mouse; collagenase; stromelysin; synovial membrane; joint; arthritis; osteoarthritis; rheumatoid arthritis; autoimmune disease; allergy; inflammation;
The concentration of ribozyme required to affect a therapeutic treatment is lower than that required of antisense molecules, and is highly specific. The present sequence is used in the exemplification of the present invention
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Enzymatic nucleic acid molecules having a hammer-head motif - used for
the treatment of arthritis, induction of graft tolerance or treatment
                                                                                                                                                                                                                                       Gaps

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Enzymatic nucleic acid molecules having a hammer-head motif - used for the treatment of arthritis, induction of graft tolerance or treatment of auto-immune diseases.
be used to treat antigen presenting cells of a donor to induce tolerance in a recipient to an alloantigen of a donor. They can also be used for treating articipant tolerance or for treating autoimmune disease, and for treating allergies and other inflammatory conditions. The ENA's can also be used in diagnosis. Ribozyme therezpy impacts on the expression of stromelysin without introducing the non-specific effects upon gene expression which accompany treatment with retinoids and dexamethasone. The concentration of fibozyme required to affect a therspectic treatment is lower than that required of antisense molecules, and is highly specific. The present sequence is used in the exemplification of the

the present inventors a concerning a concerning to the present inventors and concerning the present inventors and (iv) a 1-C-allyl modification at position 4 of the ENA, (iii) at least ten 2-O-methyl modifications; and (iv) a 3'-end modification. The ENA's can inhibit collagenase and stromelysin production in the symbolic consistency of joints for the treatment or prevention of arthritis, and show that it is not concerned to the concerning of a donor to induce tolerance in a recipient to an alloantigen of a donor. They can also be used for enhancing graft tolerance or for treating autoimmune disease, and for treating allerances or for treating autoimmune disease, and for treating allerance or for treating autoimmune disease, and for treating allerance or for treating autoimmune disease, and for treating allerances or for treating autoimmune disease, and for treating allerance in diagnosis. Ribozyme therapy impacts on the expression of stromelysin without introducing the non-specific effects upon gene expression which accompany treatment with retinoids and dexamethasone. The concentration of ribozyme required to affect a therapeutic treatment is lower than that required of antisense molecules, and is highly specific. The present sequence is used in the exemplification of the
                                                                                                                                                                                                                                                                                                                                                                                                                                   ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Arthritic condition; graft tolerance; immune response; target; cleavage; hammerhead ribozyme; hairpin ribozyme; human; rabbit; mouse; collagenase; stromelysin; synovial membrane; joint; arthritis; osteoarthritis; rheumatoid arthritis; autoimmune disease; allergy; inflammation;

The present invention describes a novel enzymatic nucleic acid (ENA) having a hammerhead motif (HM) comprising; (i) at least 5 ribose residues (i) at 2-C-allyl modification at position 4 of the ENA; (iii) at least ten 2-C-methyl modifications; and (iv) a 3-end modification. The ENA's can inhibit collagenase and stromelysin production in the synovial membrane of joints for the treatment or prevention of arthritis, particularly ostecarthritis or rheumatoid arthritis. The ENA's can also be used to treat antigen presenting cells of a donor to induce tolerance of an alloantigen of a donor. They can also be used for centaing altergies and other inflammatory conditions. The ENA's can also be used in diagnosis. Ribozyme therapy impacts on the expression of stromelysin without introducing the non-specific effects upon gene expression which accompany treatment with retinoids and dexamethasone. The concentration of ribozyme required to affect a therapeutic treatment is lower than that required of antisense molecules, and is highly specific. The present sequence is used in the exemplification of the
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Prodn. of nucleoside dimers with methylenedioxy linkage - by reacting 5'-protected nucleoside 3'-methylthio:methyl ether and 3'-protected nucleoside with bromine.
           Enzymatic nucleic acid molecules having a hammer-head motif - used for the treatment of arthritis, induction of graft tolerance or treatment of
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      OCH2O linkage; analogue; 2,6-diethylpyridine; DEP; molecular sieve;

Prodn. of nucleoside dimers with methylenedioxy linkage - by reacting 5'-protected nucleoside 3'-methylthio:methyl ether and 3'-protected nucleoside with bromine.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    The invention relates to a method for linking a first nucleoside or oligonucleotide to a second nucleoside or nucleotide through an OCH20 linkage, erating with a 5-protected nucleoside or nucleotide which is derivatised in the 3' position with an OCH28Me group. The method comprises (a) treating the derivatised nucleoside or nucleotide and a 3'-protected nucleoside or nucleotide and en a 3'-diethylpyridine (DEP) and molecular sieves; and (b) treating the protect with tetrabutylammonium fluoride (TBAF) in tetrahydrofuran (THF). The
                                   The invention relates to a method for linking a first nucleoside or oligonucleotide to a second nucleoside or nucleotide through an OCH2O linkage, starting with a 5'-protected nucleoside or nucleotide which is derivatised in the 3'-position with an OCH32Me group. The method comprises (a) treating the derivatised nucleoside or nucleotide and a 3'-protected nucleoside or nucleotide with bromine in the presence of 2', diethylpyridine (DEP) and molecular sleves; and (b) treating the product with tetrabutylammonium fluoride (TBAF) in tetrahydrofuran (THF). The OCH2O-linked dimers can be used in the synthesis of oligonucleotide analogues (containing thioformacetal linkages) e.g. useful as diagnostic agents (see WO9106629)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          OCH2O linkage, analogue, 2,6-diethylpyridine, DEP; molecular sieve;
terraburylammonium fluoride, TBAF; tetrahydrofuran; chemical synthesis;
THF: thioformacetal linkage; diagnostic agent; ss.
                                                                                                                                                                                                                                                                                                                            Gaps
                                                                                                                                                                                                                                                                                                                              ö

                                                                              ઠે
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   g
             임
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             The invention relates to a method for linking a first nucleoside or oligonucleotide to a second nucleoside or nucleotide through an OCH2O linkage, starting with a 5'-protected nucleoside or nucleotide which is derivatised in the 3' position with an OCH2SMe group. The method protected nucleoside or nucleotide and a 3'-protected nucleoside or nucleotide with bromine in the presence of 2,6 diethylpyridine (DEP) and moleotide with bromine in the presence of 2,6 with tetrabutylammonium fluoride (TBAF) in tetrahydrofuran (THF). The orthologues (containing thioformacetal linkages) e.g. useful as diagnostic agents (see WO9106629)
                                                                                           .

  OCH2O-linked dimers can be used in the synthesis of oligonucleotide analogues (containing thioformacetal linkages) e.g. useful as diagnostic agents (see WO9106629)

The invention relates to a method for linking a first nucleoside or oligonucleotide to a second nucleoside or nucleotide through an OCH2O linkage, starting with a 5'-protected nucleoside or nucleotide which is derivatised in the 3' position with an OCH2SMe group. The method comprises (a) treating the derivatised nucleoside or nucleotide and a 3'-protected nucleoside or nucleotide with bromine in the presence of 2,6-protected nucleoside or nucleotide with bromine in the presence of 2,6-with tetrabutylammonium fluoride (TBAF) in tetrahydrofuran (THF). The OCH2O-linked dimers can be used in the synthesis of oligonucleotide and analogues (containing thioformacetal linkages) e.g. useful as diagnostic
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  Prodn. of nucleoside dimers with methylenedioxy linkage - by reacting 5'-protected nucleoside 3'-methylthio:methyl ether and 3'-protected

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    셤
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        ò
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Specifically designed oligodeoxyribonucleotides form triplexes in single-
or double-strand DNA at homopurine-homopyrimidine targets. These
triplexes block in vitro DNA synthesis by all DNA polymerases studied,
including Sequenases. Taq, vent, and Pol I. A similar phenomenon occurs
when DNA polymerases are supplemented with accessory replication
proteins, including SBS protein. Replication blockage is highly sequence-
specific and even one or two point substitutions within either the target
sequence or the oligonucleotide abolish the effect. Sequence-specific
blocking of DNA replication in vivo is facilitated by the methods and
compositions of the present invention. The present sequence is the ORF-Bc
human papilloma virus (HPV) target (position 436-452 in HPV57 and 438-452
in HPV2) for triplex-forming oligonucleotides AAT35030-31
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Hammerhead ribozyme; cholesterol ester transfer protein; mRNA cleavage; neutral lipid transfer; plasma lipoprotein; atherosolerosois; atherectomy; reverse cholesterol transport; high density lipoprotein; therapy; CETP; familial hypercholesterolaemia; dyslipidaemia; hypoalphalipoproteinaemia; peripheral peripheral vascular disease; hyperchilpoproteinaemia; angioplastic restenosis; low density lipoprotein; diabetes; HDL; rabbit; LDL; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Sequence specific inhibition of DNA synthesis - by triplex-forming oligo:nucleotide(s), for detection of oncogene mutation(s) and treatment of e.g. HSV, Hepatitis C and Papillomavirus infection.

AAT50138-T50359 represent target sequences for the rabbit cholesterol ester transfer protein (CETP) hammerhead (HH) ribozymes (see AAT50360-T50546). CETP is a 74 kD glycoprotein that facilitates neutral lipid transfer between plasma lipoproteins. The numbering of the targets refers to the position of the cleavage site in full length CETP. The ribozymes are able to cleave mRNA from the gene encoding CETP, thereby blocking should transport (RCT) pathway can be inhibiting CETP, the reverse cholesterol transport (RCT) pathway can be inhibited (or eliminated) thereby preventing the reduction in size density of the high density lipoproteins (HDL), prolonging HDL half life, and therefore increasing HDL levels. The ribozymes can be used to treat conditions associated with apperchalegerolaemia, peripheral vascular disease, dyelipidaemia, hyperhotalipoproteinaemia, hypoalphalipoproteinaemia, vascular complications of diabetes, transplant, atherecomy and angioplastic restenosis. By inhibiting CETP, the levels of HDL and low density lipoproteins (LDL), and the HDL:LDL ratio are favourably altered (a cestenosis. By inhibiting CETP, the levels of cutdy genetic drift and mutations in diseased cells, and to detect CETP mRNA. As the HH ribozymes transplant can also be used diagnostically to study genetic drift and mutations in diseased cells, and to detect CETP mRNA. As the HH ribozymes
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Hammerhead ribozyme; cholesterol ester transfer protein; mRNA cleavage; neutral lipid transfer; plasma lipoprotein; atherosclerosis; atherectomy; reverse cholesterol transport; high density lipoprotein; therapy; CBTP; familial hypercholesterolaemia; dyslipidaemia; hypoalphalipoproteinaemia; peripheral vascular disease; hyperbetalipoproteinaemia; RCT; inhibitor;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      New ribozyme(s) for cleaving cholesterol ester transfer protein mRNA useful for preventing or treating initial development, progression or regression of vascular diseases, esp. familial hypercholesterolaemia.

AATS0138-T50359 represent target sequences for the rabbit cholesterol ester transfer protein (CETP) hammerhead (HH) ribozymes (see AATS0360-T50560, CETP is a 74 kb glycoprotein that facilitates neutral lipid transfer between plasma lipoproteins. The numbering of the targets refers to the position of the cleavage site in full length CETP. The ribozyme chan binds to 5 nucleotides either side of this site. The ribozyme are able to cleave mWA from the gene encoding CETP, thereby blocking synthesis and/or expression of the mRNA. By inhibiting CETP, the reverse cholesterol transport (RCT) pathway can be inhibited (or eliminated) thereby preventing the reduction in size density of the high density lipoproteins (HDL), prolonging HDL half life, and therefore increasing HDL levels. The ribozymes can be used to treat conditions associated with abnormal levels of CETP, specifically atherosclerosis, familial hypercholesterolaemia, peripheral vascular disease, dyslipidaemia, hypercholesterolaemia, peripheral vascular disease, dyslipidaemia, hyperbealipoproteinaemia, hypoalphalipoproteinaemia, and her HDL.LDL ratio are favourably altered (a ceptenosis in INL levels in the levels of HDL pare favourably altered (a ceptenosis in INL levels)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    decrease in LDL levels, and a corresponding increase in HDL levels). The HH ribozymes can also be used diagnostically to study genetic drift and mutations in diseased cells, and to detect CETP mRNA. As the HH ribozymes target specific regions of the CETP gene, they have low non-specific
angioplastic restenosis; low density lipoprotein; diabetes; HDL; rabbit;
                                                                                                                                                                                                                                                                                                                                                                                                                                  New ribozyme(s) for cleaving cholesterol ester transfer protein mRNA useful for preventing or treating initial development, progression or regression of vascular diseases, esp. familial hypercholesterolaemia.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Gaps

ANA ANA 9608-T49863 represent target sequences for the human cholesterol cster transfer protein (CETP) hammerhead (HH) ribozymes (see AAT49881-CET 50137). CETP is a 74 KD Glycoprotein that facilitates neutral lipid to the bosition of the cleavage site in full length CETP. The ribozyme crot to the position of the cleavage site in full length CETP. The ribozyme crot binds to 5 nucleotides either side of this site, provided the sequence UH is immediately upstream. The ribozymes are able to cleave mRNA from the crot simmediately upstream. The ribozymes are able to cleave mRNA from the crot simmediately upstream. The ribozymes are able to cleave mRNA from the crot is immediately upstream. The ribozymes and/or expression of the can be inhibited (or eliminated) thereby preventing the reduction in size density of the high density lipoproteins (HDL), prolonging HDL half life, and therefore increasing HDL levels. The ribozymes and be used to treat conditions associated with abnormal levels of CETP, specifically familial hypercholesteroloesterolemmia, hyposlaphalipoproteina was understood of censity lipoproteins of diabetes, transplant, atherectory and angioplastic restenosis. By inhibiting CETP, the levels of HDL and Low conditions can also be used diagnostically to study genetic drift cribozymes target specific regions of the CETP gene, they have low non-confice argeting procedure of the CETP gene, they have low non-confice arget specific activity
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  ô

```
AAT50138-T50359 represent target sequences for the rabbit cholesterol ester transfer protein (CETP) hammerhead (HH) ribozymes (see AAT50360-T50546). CETP is a 74 kD glycoprotein that facilitates neutral lipid transfer between plasma lipoproteins. The numbering of the targets refers to the position of the clavage site in full length CETP. The ribozyme then binds to 5 nucleotides either side of this site. The ribozyme able to cleave mRNA from the gene encoding CETP, thereby blocking synthesis and/or expression of the mRNA. By inhibiting CETP, the reverse cholesterol transport (RCT) pathway can be inhibited (or eliminated) thereby preventing the reduction in size density of the high density lipoproteins (HDL), prolonging HDL half life, and therefore increasing HDL levels. The ribozymes can be used to treat conditions associated with abnormal levels of CETP, specifically atherosolerosis, familial.

Bisgaier C,

hypercholesterolaemia, peripheral vascular disease, dyslipidaemia, hypercholesterolaemia, peripheral vascular disease, dyslipidaemia, hypercholesterolaemia, vascular complications of diabetees, transplant, atherectomy and angioplastic restenosis. By inhibiting CETP, the levels of HDL and low density lipoproteins (DDL), and the HDL:LDL ratio are favourably altered (a decrease in LDL levels, and a corresponding increase in HDL levels). The HH ribozymes can also be used diagnostically to study genetic drift and mutations in diseased cells, and to detect CETP mRNA. As the HH ribozymes target specific regions of the CETP gene, they have low non-specific

AATS0138-T50359 represent target sequences for the rabbit cholesterol cester transfer protein (CETP) hammerhead (HH) ribozymes (see AAT50360-CTP is a 74 kD glycoprotein that facilitates neutral lipid transfer between plasma lipoproteins. The numbering of the targets refers to the position of the cleavage sither in full length CETP. The ribozyme are able to cleave mRNA from the gene encoding CETP, thereby blocking cynthesis and/or expression of the mRNA. By inhibiting CETP, the reverse cholesterol transport (RCT) pathway can be inhibited (or eliminated) thereby preventing the reduction in size density of the high density conclusions (HDL), prolonging HDL half life, and therefore increasing HDL levels. The ribozymes can be used to treat conditions associated with abnormal levels of CETP, specifically atherosclerosis, familial compulsations of diabetes, transplant, atherosclerosis, familial hyperchelesterolaemia, hypoalphalipoproteinaemia, vascular compulsations of diabetes, transplant, atherectomy and angioplastic restenosis. By inhibiting CETP, the levels of HDL and low density compulsations (LDL), and the HDL:LDL ratio are favourably altered (a decrease in LDL), and a corresponding increase in HDL levels). The HT ribozymes can also be used diagnostically to study genetic drift and materions in diseased cells, and to detect CETP mRNA. As the HH ribozymes can also be used diagnostically to study genetic drift and reference transplat specific

```
The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-
2'deoxyuzidine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine and uridine contraining an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primars for specific RNA or DNA. (Updated on 25-NAR-2003 to correct PF field.)

The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  ö
                                                                                                                                                                     Modification, triplex, duplex, nucleomonomer analogue, unsaturated group, pyrimidine ring, inhibition, gene expression, antisense, therapy, research, diagnosis, probe, primer, ss.
                                                                                                                                                                                                                                                                                                Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  Gaps

                                                                                                                                                                                                                                                                                                                                                                                                                                                                           The present sequence is a 5-(1-propynyl)-2'-deoxycytidine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of suptosine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                    Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.

The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        group;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      The present sequence is a 5-(1-propynyl)-2'-deoxycytidine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      The present sequence is a 5-methyl-2'-deoxycytidine/5-(2-thienyl)-2'deoxyuridine modified triplex forming oligonucleotide, comprising nucleomnomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PP field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                    Location/Qualifiers

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              ò
                                                                                                                                                                                                                                                                                         The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'deoxyuridine modified triplex forming oligomuclectide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substitutent provides enhanced binding capacity in the primidine fungiones and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance call permearion and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  ö

The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'deoxyuridine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituted provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.

The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'deoxyuridine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      The present sequence is a 5-methyl-2'-deoxycytidine/5-(2-pyridinyl)-2'deoxyuridine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. The present sequence is a 5-(1-propynyl)-2'-O-allyldeoxycytidine modified triplex forming oligonucleotide, comprising nucleomonmer analogues of sytosine containing an unsaturated group in the pyrimidine ring. The 5-dubstituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense condiguration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  Modification, triplex, duplex, nucleomonomer analogue, unsaturated group, pyrimidine ring, inhibition, gene expression, antisense, therapy; research, diagnosis, probe, primer, ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               RESULT 1548
g
```

```
The present sequence is a 5-(2-pryridinyl)-2'-deoxycytidine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of suptraine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA, (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.

The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'deoxyuridine modified triplex forming oligonucleotide, comprising uncleomnomer analogues of cytosine and utidine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PP field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.
                                                                                                                                                                                                                  Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Pyrimidine ring modified triplex forming oligonucleotide ON-1.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         8
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         ö
                                                                                                                                                                                                                                                                                                                                                                                       The present sequence is a 5-(1-propynyl)-2'-deoxycytidine/5-(1-propynyl)-2'-deoxycytidine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological ph conditions. The lipophilic groups can also enhance cell permeation and upteake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal coligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Modification, triplex, duplex, nucleomonomer analogue, unsaturated group, pyrimidine ring, inhibition, gene expression, antisense, therapy; research, diagnosis, probe, primer, ss.
